

Launch Readiness & Solutions

Verified against the live site at mutxriterminal.com on 30 August 2026. Every figure below was measured, not estimated.

Verdict

The data layer is sound and ready to show people. Prices are exact against both independent sources, the panels agree with each other, and there is no fabricated data anywhere in the 1,465 financial statement files. **Two things block launch:** nobody can sign up, and four shipped features have been reverted on production. Neither is a data problem.

Area	State	Evidence
Prices	PASS	145/145 NGX match the exchange's own price list; 8/8 JSE match Yahoo to the cent
Panel consistency	PASS	821 heatmap cells vs watchlist — 0 disagreements, 0 impossible moves
Financial statements	PASS	540 index entries, 0 with no file behind them; 1,465 files, 0 artefact values
Charts	PASS	682 chartable, 339 showing the honest no-history card, 0 corrupt files
Sign-up	BLOCKER	Calls /api/auth/ — no backend deployed. Returns “Could not reach the server.”
Shipped features	BLOCKER	4 features reverted on production by a concurrent deploy
Secondary panels	GAPS	CORP indices blank, GLCO gold has no price, NEWS empty
Logos	GAPS	648/1,021 have a logo; 252 EGX securities have no domain source

Blockers — fix before anyone gets the URL

1. Nobody can sign up

The landing page collects an email and a password, posts to /api/auth/, and shows “Could not reach the server. Try again shortly.” The endpoint lives in `auth_api.py`, which is not deployed anywhere. Every sign-up fails.

Solution — no backend, no monthly cost:

Step	What to do
1	Create a free Supabase project. It gives you Postgres plus hosted auth (email verification, password reset, OAuth) — none of which <code>auth_api.py</code> has.
2	Point the landing form at Supabase's client library instead of /api/auth/. The browser talks to it directly with a public anon key; no server process.
3	Enable Row Level Security on the users table before going live — it is off by default.

This also retires a latent bug: `_SESSIONS = {}` in `auth_api.py` is an in-process dictionary, so every restart would log out all users and it breaks outright on a second instance.

2. Four shipped features are reverted on production

A second agent working in this repository deployed `index.html` over the version carrying these features. All four are confirmed absent from the live site right now.

Feature	Was working	Live now
Financial statements in the Market rail	yes	gone
Per-security chart in the Market rail	yes	gone
FINANCIALS panel follows the watchlist selection	yes	gone
“(derived)” label on estimated share counts	yes	gone

Solution: stop the second agent, or give it and this session separate files. Re-applying the features without that produces a fourth revert. The code is recoverable from git history — the loss is the deploy race, not the work. Shares outstanding survives because the other agent implemented its own version of that row.

Secondary fixes — worth doing, not blocking

Issue	What a user sees	Solution
CORP indices	“FTSE/JSE All Share — —”. Gainers, losers and movers below it all work.	Point the block at indices.json, which already carries JSE Top 40, All-Share and Top40 USD.
GLCO gold	Gold shows no price; platinum, silver, Brent and WTI all show one.	One missing symbol in the commodities fetch. Also review the +12% and +15% metal moves — those look like period changes labelled as daily.
NEWS panel	“no free news feed for JSE” — honest, but empty on every exchange.	Either wire a free RSS source or drop the tab until it has content. An empty tab reads as broken.
EGX logos	252 of 374 EGX securities show a letter monogram.	No domain source exists — company_info.json holds zero EGX entries. Needs a one-off domain list. Do not guess: name-matching is what previously put Equity Group's logo on three unrelated securities.
Airtel Africa	Figures labelled NGN; the company reports in USD.	AfricanFinancials leaves currency null and the build defaults by exchange. Add a per-security currency override.

Data ceilings — not bugs, and already labelled honestly

These are the limits of what is publicly available for free. The terminal already tells the user rather than filling the gap with an estimate, which is the right behaviour. They are listed so you are not surprised when a customer asks.

Coverage	JSE	EGX	NGX	NSE	Why
Listed	431	374	152	64	—
With a price	360	251	149	61	EGX gap is ISIN-coded lines Yahoo does not carry
Chartable	285	243	135	19	NSE: ir.nse.co.ke now serves only its own ticker
Statements	276	89	123	52	NGX/NSE from AfricanFinancials filings
Share count	271	88	127	61	NGX derived from market cap / price
Logo	327	122	136	63	Monogram fallback where absent

NSE Kenya history cannot be backfilled

The archive was built from ir.nse.co.ke, which now returns 406 for every symbol except the NSE's own — its widget builds the URL from a client code, not the ticker. mystocks' history pages are 404, afx.kwayisi is unreachable, and Yahoo does not list Nairobi at all. **Solution:** append_nseBars.py records one official board

bar per run, so the archive grows forward from today. The 19 deep names are intact. To fix it faster you need a paid feed or a data-sharing arrangement with the exchange.

Infrastructure — the \$0 launch path

You do not need to run a backend. The terminal is fully static, already live on GitHub Pages behind Cloudflare, and reads JSON snapshots with no API calls. A server process is the only thing here that would cost money, so do not have one yet.

Piece	Where	Cost
Terminal + landing page	GitHub Pages — already there	\$0
Database + auth	Supabase free tier	\$0
Payments	Stripe Checkout / Payment Links	~2.9% + 30¢ per sale
Stripe webhook	Supabase Edge Function or Cloudflare Worker	\$0

Why Postgres and not MongoDB

Mongo is already scaffolded here, so this is a deliberate change of direction. Payments need guarantees that Postgres gives for free and Mongo makes you hand-roll: a unique constraint on email, a foreign key from subscription to user, a check constraint on status, and `INSERT ... ON CONFLICT DO NOTHING` on the Stripe event id — that one line is your entire webhook idempotency story. Stripe retries aggressively; without it you double-credit people. Volume is irrelevant either way at hundreds of users, so choose on correctness.

Keep market data out of the database entirely. `sync_to_mongodb.py` exists to avoid shipping large JSON files, but that trades a free CDN read for a paid round trip and adds a failure mode where the terminal goes blank if the database hiccups. The deploy-size problem it solves is already handled by `deploy_changed.py`, which pushes only changed files.

Never store card data. Stripe Checkout, and you keep only the customer id and subscription status.

Render vs Vercel, when you do need a backend

Render. `afri_server.py` is a `stdlib ThreadingHTTPServer` — one long-running process. Vercel runs serverless functions and would need every route rewritten. Render runs it as-is, and `backend_render/` already holds `render.yaml`, a `Dockerfile`, `requirements.txt` and a health check. Budget ~\$7/month for the Starter plan: the free tier sleeps after 15 minutes, so your first visitor waits 50+ seconds, and Render's free Postgres expires after 30 days. The only thing that forces this decision is wanting live intraday quotes instead of end-of-day snapshots — a product choice, not a launch requirement.

One caveat on the day-change figure

Yahoo leaves the last session or two null in its daily array while still knowing their closes. The change was being recomputed against the previous *populated* bar, so it silently spanned the gap — Sasol read +4.90% for a two-session move. This is fixed: each bar now carries the provider's own reported day change and the build uses it.

Stated precisely: the number is now the provider's own day figure rather than our arithmetic across a hole, which is better provenance. It is *not* independently verified — Yahoo is the only source for JSE and EGX, and its own fields contradict each other (`chartPreviousClose` is range-dependent and disagrees with `regularMarketChangePercent` for the same security). Treat JSE/EGX day changes as provider-reported. NGX is the one exchange where the change is verified against the exchange's own published price list.

Suggested order

#	Action	Effort
1	Stop the second agent, or split the files it and this session touch	minutes
2	Wire sign-up to Supabase and confirm a real account is created	1–2 hours
3	Re-apply the four reverted features once the deploy race is settled	30 minutes
4	Fix CORP indices and GLCO gold; hide NEWS until it has content	1 hour
5	Launch read-only with the waitlist working	—
6	Add Stripe once people are asking to pay	later

All figures measured against the live site on 30 August 2026. Coverage counts come from a full sweep of static_data; price checks compare against the NGX's published price list and Yahoo Finance.
